

# Right Heart Catheterization

## Swan Ganz Catheter

- A 120-cm long, multi-lumen, balloon-tipped catheter. Usually 7.5 fr.
- Connected to a pressure transducer and temperature sensor.
- Inserted through a central venous access (R IJ, L subclavian, femoral vein).
- Waveforms rise and fall due to  $\Delta$  blood volume or  $\Delta$  myocardial fiber tension (ie. chamber size)
- Appropriate flushing, leveling and zeroing at Phlebostasis axis (Mid axillary line x 4th ICS)
- Help in dx types of shock, type of pul edema, dx L $\rightarrow$ R shunt, pul HTN, hemodynamic tailored therapy in HF.
- No benefit in RCT of ADHF (ESCAPE JAMA 2005) and should not be routinely use (Ann Int Med 1985;103:445, Am J Med 2005 118, 449)

## Tips

- Time the wave with the ECG. Pressure waveforms are slightly delay after ECG.
- Use all numbers together and observe changes or trends.
- The waveform morphology is important. (Am J Med 1987.83;111).
- Know which numbers are directly measured, which numbers are from calculation!
- On round, present RA, PA, PCWP, CI, and SVR then add other paramethers (TPG, PVR) if relevant.

RA (6 mmHg)	RV (24/6 mmHg)	PA (24/12 mmHg)	PCWP (12 mmHg)
<ul style="list-style-type: none"> <li>• Venous waveform (2 up, 2 down per cardiac cycle)</li> <li>A: Atrial systole                             <ul style="list-style-type: none"> <li>- Increased in RV infarct, PS, PE, Pul HTN</li> <li>- Giant Cannon a waves in A-V dissociation, 3' AV block, VT</li> </ul> </li> <li>X: atrial relaxation                             <ul style="list-style-type: none"> <li>- Increase in restrictive and constrictive disease</li> <li>- Decrease in severe tricuspid regurgitation</li> </ul> </li> <li>C: bulging of the AV valve</li> <li>V: filling of atrium (atrial diastole)                             <ul style="list-style-type: none"> <li>- large C-V waves in TR</li> </ul> </li> <li>Y: emptying of the RA into RV                             <ul style="list-style-type: none"> <li>- Increase in early restrictive, severe TR</li> <li>- Blunted in TS, RV infarct and frank tamponade.</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Rapid upstroke followed by a rapid downstroke. ## Common pitfalls

- Failure to level
- Dampening due to air in the system
- Not measuring at end expiration (high point in spontaneous breathing. Sunrise and Valley)
- Partial wedge (in PH)
- Use computer reading number
- ? Subtract 1/2 PEEP from the values.
- 10 cm H2O = 7.35 mmHg

**Flow:** Cardiac output (CO, L/min) are commonly indirectly "measured" by

<p><b>CO by thermodilution:</b></p> <ul style="list-style-type: none"> <li>• Indicator dilution method</li> <li>• Injecting known amount and temp of fluid to a proximal port and measure <math>\Delta</math> temp at distal port.</li> </ul> <p style="text-align: center;">CO = Reverse area under the curve</p> <ul style="list-style-type: none"> <li>• Limit in TR, shunt, low CO, rhythm disturbances, incorrect constant number. (Crit Care Med 1993; 21:586)</li> </ul>	<p><b>CO by Fick: "Gold standard"</b></p> <ul style="list-style-type: none"> <li>• Constant of mass</li> <li>• Measure O2consumption, SaO2sat, MvO2Sat, and Hb.</li> </ul> <p style="text-align: center;">CO = O2 consumption / A-V O2 difference = <math>\frac{VO_2}{10 \times 1.34Hb(SaO_2 - MvO_2Sat)}</math></p> <ul style="list-style-type: none"> <li>• Limit in shunt, inaccurate assumption of VO2 (circ 2014;129:203)</li> </ul>
---	---

**Hemodynamics:** Know the unit, understand the relations (formula)

Parameter and relations	Normal value and unit
$V = IR$	$\Delta BP = CO \times SVR$
CO	= 5 L/min
BSA	= 2 m <sup>2</sup>
$CI = \frac{CO}{BSA}$	= 2.5 L/min/m <sup>2</sup>
HR	= 70 bpm
$SV = \frac{CO}{HR}$	= 70 ml/beat
$SVI = \frac{SV}{BSA}$	= 35 ml/beat/m <sup>2</sup>
$SVR = \frac{(MAP - CVP) \times 80}{CO}$	= 1300 dynes.sec/cm <sup>5</sup>
$PVR = \frac{(mPA - PCWP)}{CO}$	= 1 wood unit
TPG = mPA - PCWP	= 5 mmHg
Ao	= 120/80 mmHg
A O2sat	= 95-100 %
Mixed V O2sat	= 75 %
A - V O2 content difference	= 20 - 15 = 5 ml/dL
$EF = \frac{LVEDV - LVESV}{LVEDV}$	
LWSWI = SVI x (MAP-PCWP) x 0.0136	= 50 - 62 g/m <sup>2</sup> /beat
RVSWI = SVI x (mPA-CVP) x 0.0136	= 5-10 g/m <sup>2</sup> /beat

## Shunt Study "Sat run":

- O2 saturations were measured from multiple site of the heart.
- A step-up in O2Sat of >7% (RA level), 5% (RV or PA level) indicate left to right shunt.

- Inpatient with shunt
  - CO by TD is inaccurate
  - CO by Fick need to use calculated mixed venous sat

Shunt calculation

- $MvO_2Sat = \frac{(3SVC + 1IVC)}{4}$
- $Q_s = \frac{(O_2 \text{ consumption})}{(13.4 \times Hgb \times (AO_2 - MvO_2Sat))}$
- $Q_p = \frac{(O_2 \text{ consumption})}{(13.4 \times Hgb \times (PVO_2 - PAO_2Sat))}$
- Simplified  $Q_p/Q_s = \frac{(AO_2 - MvO_2Sat)}{(PVO_2 - PAO_2Sat)}$
